Component Diagram:

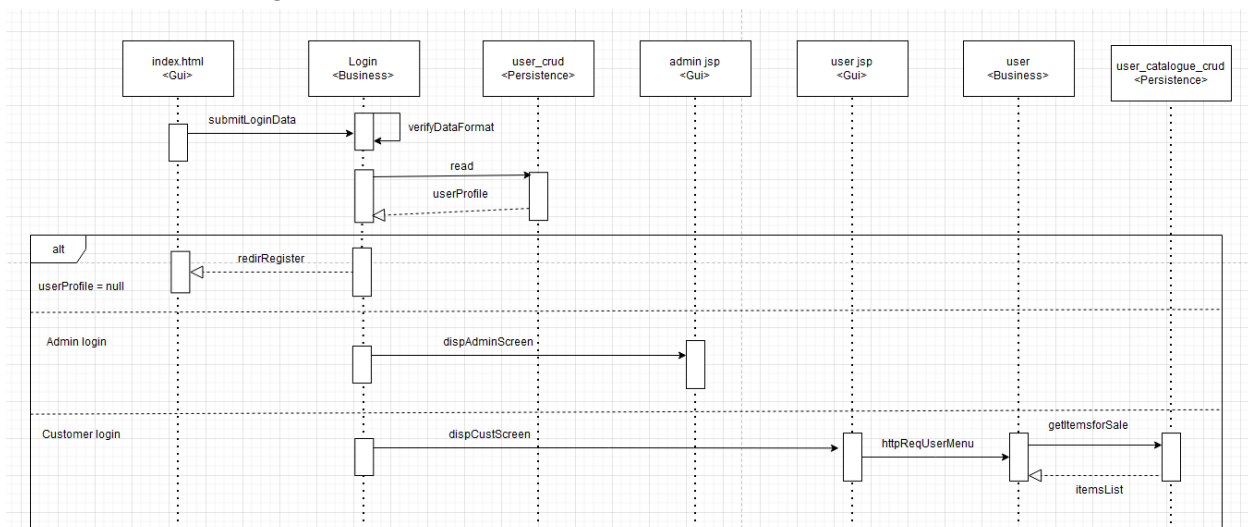

Sequence Diagram:

Use case 1: User registers for an account

1. User starts at the main index page
2. User selects the customer registration page option
3. Index object captures the request, calls the “httpRequestReg” method to retrieve the customer registration page
4. User fills in the registration form and provides their first name, last name, address, city, province/state, country, email, username, password, and agrees to the terms and conditions. submitformData will send the information to the custRegister object to verify form data and create a UserData object (helper class)
5. custCreate_crud will capture the data inside the UserData object and store it into a database, then perform the createCustTrue and redirect user to the page which will confirm that the account has been created
 - a. If account failed to create, user will be redirected to the original registration page to try again

Use case 2: Account login

1. User starts at the main index page
2. User stays on the page, enters login information
3. Login object captures the submitted data, verifies the format of the data (ex. Emails are email format)
4. Once data is valid, call the “read” method to compare the given information against the ones in the user info database. A userprofile will be returned to Login object.
 - a. If no user profile was found, user will be re directed to the main login page to try again
 - b. If the person logging is an admin, they will be re directed to the admin login page
 - c. If the person logging in is a customer, they will be re directed to the user page, where “httpReqUserMenu” will be called to display the possible user options. This includes displaying the items on sale, which will be shown after “getItemsforSale” is called, and a list is returned through “itemList”
